CROSS REFERENCE

This is a continuation-in part of co-pending application U.S.S.N. 08/406,619, filed March 20, 1995, which is hereby incorporated by reference.

BACKGROUND OF THE INVENTION

Nodulosporic acid and two related components are antiparasitic agents and ectoparasiticidal agents isolated from the fermentation culture of *Nodulisporium* sp. MF-5954 (ATCC 74245). These three compounds have the following structures:

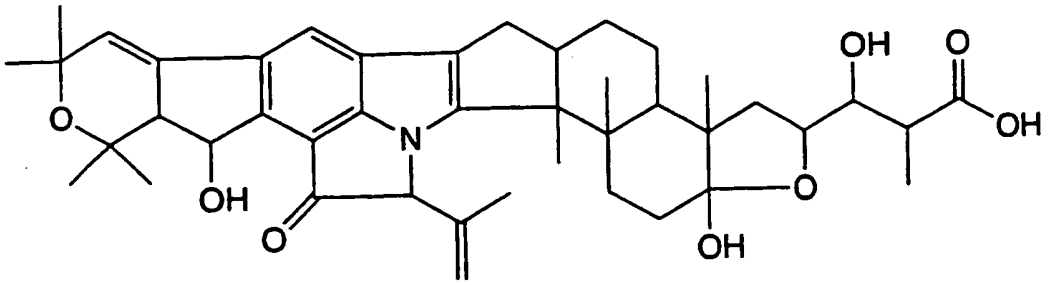
31-hydroxy-20,30-oxa-29,30,31,32-tetrahydro-nodulisporic acid (compound C)



SUMMARY OF THE INVENTION

This invention relates to new acaricidal, antiparasitic, insecticidal and anthelmintic agents related to the nodulisporic acids, to processes for their preparation, compositions thereof, their use in the treatment of parasitic infections, including helminthiasis, in human and animals, and their use in the treatment of parasitic infections in plants or plant products.

MF-5954 (ATCC 74245). The description of the producing microorganism, the fermentation process, and the isolation and purification of the three nodulisporic acids are disclosed in US Patent 5,399,582, issued March 21, 1995, which is hereby incorporated by reference in its entirety.

The above structural formula is shown without a definitive stereochemistry at certain positions. However, during the the course of the synthetic procedures used to prepare such compounds, or using racemization or epimerization procedures known to those skilled in the art, the products of such procedures can be a mixture of stereoisomers. In particular, the stereoisomers at C1, C4, C20, C26, C31 and C32 may be oriented in either the alpha- or beta-position, representing such groups oriented below or above the plane of the molecule, respectively. In each such case, and at other positions in the molecule, both the alpha- and beta-configurations are intended to be included within the ambit of this invention.

Compounds of formula I wherein the allyl group at position 26 is in the epi configuration may be obtained by treatment of the appropriate precursor with a bases such as hydroxide, methoxide, imidazole, triethylamine, potassium hydride, lithium diisopropylamide and the like in protic or aprotic solvents (as appropriate) such as water, methanol, ethanol, methylene chloride, chloroform, tetrahydrofuran, dimethylformamide and the like. The reaction is complete at temperatures from -78°C to the reflux temperature of the solution in from 15 minutes to 12 hours.

Compounds of formula I where R_2 (and R_1 is hydrogen), R_3, R_4 and R_8 independently are hydroxy may be inverted by treatment of the appropriate alcohol using protocols known to those skilled in the art. For example, the alcohol may be reacted under Mitsunobu conditions with a carboxylic acid (formic acid, propionic acid, 2-chloroacetic acid, benzoic acid, para-nitro-benzoic acid and the like), a tri-substituted phosphine (triphenylphosphine, tri-n-butylphoshine, tripropylphosphine and the like) and a dialkyl diazodicarboxylate (diethyl diazodicarboxylate, dimethyl diazodicarboxylate, diisopropyl diazodicarboxylate and the like) in an aprotic solvent such as methylene chloride, tetrahydrofuran, chloroform, benzene and the like. The Mitsunobu reactions are complete in from 1 to 24 hours at temperatures from 0°C to the reflux temperature of the solution. The resultant esters may be hydrolyzed by treatment with hydroxide or ammonium hydroxide

in a protic solvent such as methanol, ethanol, water, tetrahydrofuran/water or dimethylformamide/water and the like at from 0°C to the reflux temperature of the solution. Alternatively, the resultant esters may be hydrolyzed by treatment with a Lewis acid, such as magnesium chloride, aluminum chloride, titanium tetra-isopropoxide and the like in a protic solvent such as methanol, ethanol, isopropanol and the like and the reactions are complete in from 1 to 24 hours at 0°C to the reflux temperature of the solution.

During certain reactions described below, it may be necessary to protect the groups at R_2, R_3, R_4, R_8, R_9 and R_{10}. With these positions protected, the reactions may be carried out at other positions without affecting the remainder of the molecule. Subsequent to any of the described reactions (vida infra), the protecting group(s) may be removed and the unprotected product isolated. The protecting groups employed at R_2, R_3, R_4, R_8, R_9 and R_{10} are those which may be readily synthesized, not significantly affected by the reactions at the other positions, and may be removed without significantly affecting any other functionality of the molecule. One preferred type of protecting group is the tri-substituted silyl group, preferably the tri-loweralkyl silyl group or di-loweralkyl-aryl silyl group. Especially preferred examples are the trimethylsilyl, triethylsilyl, triisopropylsilyl, tert-butyldimethylsilyl and dimethylphenylsilyl groups.

The protected compound may be prepared with the appropriately substituted silyl trifluoromethanesulfonate or silyl halide, preferably the silyl chloride. The reaction is carried out in an aprotic solvent such as methylene chloride, benzene, toluene, ethyl acetate, isopropyl acetate, tetrahydrofuran, dimethylformamide and the like. In order to minimize side reactions, there is included in the reaction mixture a base to react with the acid released during the course of the reaction. Preferred bases are amines such as imidazole, pyridine, triethylamine or diisopropylethylamine and the like. The base is required in amounts equimolar to the amount of hydrogen halide liberated, however, generally several equivalents of the amine are employed. The reaction is stirred at

from 0°C to the reflux temperature of the reaction mixture and is complete from 1 to 24 hours.

The silyl group is removed by treatment of the silyl compound with anhydrous pyridine-hydrogen fluoride in tetrahydrofuran or dimethylsulfoxide or with tetraalkylammonium fluoride in tetrahydrofuran. The reaction is complete in from 1 to 24 hours at from 0°C to 50°C. Alternatively, the silyl group may be removed by stirring the silylated compound in lower protic solvents such as methanol, ethanol, isopropanol and the like catalyzed by an acid, preferably a sulfonic acid monohydrate such as para-toluenesulfonic acid, benzenesulfonic acid or carboxylic acids such as acetic acid, propionic acid, monochloroacetic acid, dichloroacetic acid, trichloroacetic acid and the like. The reaction is complete in 1 to 24 hours at from 0°C to 50°C.

Protecting groups that may also be suitably used in the preparation of compounds of the present invention may be found in standard textbooks such as Greene and Wutz, Protective Groups in Organic Synthesis, 1991, John Wiley & Sons, Inc.

Oxime formation may be accomplished using techniques known to those skilled in the art, including, but not restricted to, the use of H_2NOR^a either as the free base or as an acid addition salt such as the HCl salt, or an O-protected hydroxylamine such as O-trialkylsilylhydroxylamine, in a protic solvent such as methanol, ethanol, isopropanol and the like or aprotic solvents such as methylene chloride, chloroform, ethyl acetate, isopropyl acetate, tetrahydrofuran, dimethylformamide, benzene, toluene and the like, as appropriate. The double bonds may be hydrogenated with any of a variety of standard precious metal hydrogenation catalysts such as Wilkinson's catalyst, Pearlman's catalyst, 1-25% palladium on carbon, 1-25% platinum on carbon and the like. The instant compounds are potent endo- and ecto-antiparasitic agents against parasites particularly helminths, ectoparasites, insects, and acarides, infecting man, animals and plants, thus having utility in human and animal health, agriculture and pest control in household and commercial areas.

The disease or group of diseases described generally as helminthiasis is due to infection of an animal host with parasitic worms known as helminths. Helminthiasis is a prevalent and serious economic problem in domesticated animals such as swine, sheep, horses, cattle, goats, dogs, cats, fish, buffalo, camels, llamas, reindeer, laboratory animals, furbearing animals, zoo animals and exotic species and poultry. Among the helminths, the group of worms described as nematodes causes widespread and often times serious infection in various species of animals. The most common genera of nematodes infecting the animals referred to above are Haemonchus, Trichostrongylus, Ostertagia, Nematodirus, Cooperia, Ascaris, Bunostomum, Oesophagostomum, Chabertia, Trichuris, Strongylus, Trichonema, Dictyocaulus, Capillaria, Habronema, Druschia, Heterakis, Toxocara, Ascaridia, Oxyuris, Ancylostoma, Uncinaria, Toxascaris and Parascaris. Certain of these, such as Nematodirus, Cooperia, and Oesophagostomum attack primarily the intestinal tract while others, such as Haemonchus and Ostertagia, are more prevalent in the stomach while still others such as Dictyocaulus are found in the lungs. Still other parasites may be located in other tissues

and organs of the body such as the heart and blood vessels, subcutaneous and lymphatic tissue and the like. The parasitic infections known as helminthiases lead to anemia, malnutrition, weakness, weight loss, severe damage to the walls of the intestinal tract and other tissues and organs and, if left untreated, may result in death of the infected host. The compounds of this invention have activity against these parasites, and in addition are also active against Dirofilaria in dogs and cats, Nematospiroides, Syphacia, Aspiculuris in rodents, arthropod ectoparasites of animals and birds such as ticks, mites such as scabies lice, fleas, blowflies, and other biting insects in domesticated animals and poultry, such as Tenophalides, Ixodes, Psoroptes, and Hemotobia, in sheep Lucilia sp., biting insects and such migrating dipterous larvae as Hypoderma sp. in cattle, Gastrophilus in horses, and Cuterebra sp. in rodents and nuisance flies including blood feeding flies and filth flies.

The instant compounds are also useful against parasites which infect humans. The most common genera of parasites of the gastro-intestinal tract of man are Ancylostoma, Necator, Ascaris, Strongyloides, Trichinella, Capillaria, Trichuris, and Enterobius. Other medically important genera of parasites which are found in the blood or other tissues and organs outside the gastrointestinal tract are the filiarial worms such as Wuchereria, Brugia, Onchocerca and Loa, Dracunuculus and extra intestinal stages of the intestinal worms Strongyloides and Trichinella. The compounds are also of value against arthropods parasitizing man, biting insects and other dipterous pests causing annoyance to man.

The compounds are also active against household pests such as the cockroach, Blatella sp., clothes moth, Tineola sp., carpet beetle, Attagenus sp., the housefly Musca domestica as well as fleas, house dust mites, termites and ants.

The compounds are also useful against insect pests of stored grains such as Tribolium sp., Tenebrio sp. and of agricultural plants such as aphids, (Acyrthiosiphon sp.); against migratory orthopterans such as locusts and immature stages of insects living on plant tissue. The compounds are useful as a nematocide for the control of soil nematodes

and plant parasites such as Meloidogyne sp. which may be of importance in agriculture. The compounds are also highly useful in treating acerage infested with fire ant nests. The compounds are scattered above the infested area in low levels in bait formulations which are brought back to the nest. In addition to a direct-but-slow onset toxic effect on the fire ants, the compound has a long-term effect on the nest by sterilizing the queen which effectively destroys the nest.

The compounds of this invention may be administered in formulations wherein the active compound is intimately admixed with one or more inert ingredients and optionally including one or more additional active ingredients. The compounds may be used in any composition known to those skilled in the art for administration to humans and animals, for application to plants and for premise and area application to control household pests in either a residential or commercial setting. For application to humans and animals to control internal and external parasites, oral formulations, in solid or liquid or parenteral liquid, implant or depot injection forms may be used. For topical application dip, spray, powder, dust, pour-on, spot-on, jetting fluid, shampoos, collar, tag or harness, may be used. For agricultural premise or area application, liquid spray, powders, dust, or bait forms may be used. In addition "feed-through" forms may be used to control nuisance flies that feed or breed in animal waste. The compounds are formulated, such as by encapsulation, to lease a residue of active agent in the animal waste which controls filth flies or other arthropod pests.

These compounds may be administered orally in a unit dosage form such as a capsule, bolus or tablet, or as a liquid drench where used as an anthelmintic in mammals. The drench is normally a solution, suspension or dispersion of the active ingredient usually in water together with a suspending agent such as bentonite and a wetting agent or like excipient. Generally, the drenches also contain an antifoaming agent. Drench formulations generally contain from about 0.001 to 0.5% by weight of the active compound. Preferred drench formulations may contain from 0.01 to 0.1% by weight. The capsules and

boluses comprise the active ingredient admixed with a carrier vehicle such as starch, talc, magnesium stearate, or di-calcium phosphate.

Where it is desired to administer the instant compounds in a dry, solid unit dosage form, capsules, boluses or tablets containing the desired amount of active compound usually are employed. These dosage forms are prepared by intimately and uniformly mixing the active ingredient with suitable finely divided diluents, fillers, disintegrating agents, and/or binders such as starch, lactose, talc, magnesium stearate, vegetable gums and the like. Such unit dosage formulations may be varied widely with respect to their total weight and content of the antiparasitic agent depending upon factors such as the type of host animal to be treated, the severity and type of infection and the weight of the host.

When the active compound is to be administered via an animal feedstuff, it is intimately dispersed in the feed or used as a top dressing or in the form of pellets or liquid which may then be added to the finished feed or optionally fed separately. Alternatively, feed based individual dosage forms may be used such as a chewable treat. Alternatively, the antiparasitic compounds of this invention may be administered to animals parenterally, for example, by intraruminal, intramuscular, intravascular, intratracheal, or subcutaneous injection in which the active ingredient is dissolved or dispersed in a liquid carrier vehicle. For parenteral administration, the active material is suitably admixed with an acceptable vehicle, preferably of the vegetable oil variety such as peanut oil, cotton seed oil and the like. Other parenteral vehicles such as organic preparation using solketal, glycerol formal, propylene glycol, and aqueous parenteral formulations are also used. The active compound or compounds are dissolved or suspended in the parenteral formulation for administration; such formulations generally contain from 0.0005 to 5% by weight of the active compound.

The agents of this invention can be used in the treatment and/or prevention of diseases caused by parasites, for example, arthropod parasites such as ticks, lice, fleas, mites and other biting arthropods in domesticated animals and poultry. The agents of this invention also are useful in the prevention and treatment of diseases caused by

helminthiasis. They are also effective in treatment of parasitic diseases that occur in other animals including humans. The optimum amount to be employed for best results will, of course, depend upon the particular compound employed, the species of animal to be treated and the type and severity of parasitic infection or infestation. Generally good results are obtained with our novel compounds by the oral administration of from about 0.001 to 500 mg per kg of animal body weight, such total dose being given at one time or in divided doses over a relatively short period of time such as 1-5 days. With the preferred compounds of the invention, excellent control of such parasites is obtained in animals by administering from about 0.025 to 100 mg per kg of body weight in a single dose. Repeat treatments are given as required to combat re-infections and are dependent upon the species of parasite and the husbandry techniques being employed. Repeat treatments may be given daily, weekly, biweekly or monthly, or any combination thereof, as required. The techniques for administering these materials to animals are known to those skilled in the veterinary field.

When the compounds described herein are administered as a component of the feed of the animals, or dissolved or suspended in the drinking water, compositions are provided in which the active compound or compounds are intimately dispersed in an inert carrier or diluent. By inert carrier is meant one that will not react with the antiparasitic agent and one that may be administered safely to animals. Preferably, a carrier for feed administration is one that is, or may be, an ingredient of the animal ration.

Suitable compositions include feed premixes or supplements in which the active ingredient is present in relatively large amounts and which are suitable for direct feeding to the animal or for addition to the feed either directly or after an intermediate dilution or blending step. Typical carriers or diluents suitable for such compositions include, for example, distillers' dried grains, corn meal, citrus meal, fermentation residues, ground oyster shells, wheat shorts, molasses solubles, corn cob meal, edible bean mill feed, soya grits, crushed limestone and the like. The active compounds are intimately dispersed throughout the carrier by

methods such as grinding, stirring, milling or tumbling. Compositions containing from about 0.005 to 2.0% weight of the active compound are particularly suitable as feed premixes. Feed supplements, which are fed directly to the animal, contain from about 0.0002 to 0.3% by weight of the active compounds.

Such supplements are added to the animal feed in an amount to give the finished feed the concentration of active compound desired for the treatment and control of parasitic diseases. Although the desired concentration of active compound will vary depending upon the factors previously mentioned as well as upon the particular compound employed, the compounds of this invention are usually fed at concentrations of between 0.00001 to 0.002% in the feed in order to achieve the desired anti-parasitic result.

In using the compounds of this invention, the individual compounds may be prepared and used in that form. Alternatively, mixtures of the individual compounds may be used, or they may be combined with other active compounds not related to the compounds of this invention.

The compounds of this invention are also useful in combatting agricultural pests that inflict damage upon crops while they are growing or while in storage. The compounds are applied using known techniques as sprays, dusts, emulsions and the like, to the growing or stored crops to effect protection from such agricultural pests.

Compounds of this invention may be co-administered with anthelmintic agents. These anthelmintic agents are meant to include, but not be restricted to, compounds selected from the avermectin and milbemycin class of compounds such as ivermectin, avermectin, abamectin, emamectin, eprinamectin, doramectin, fulladectin, moxidectin, Interceptor and nemadectin. Additional anthelmintic agents include the benzimidazoles such as thiabendazole, cambendazole, parbendazole, oxibendazole, mebendazole, flubendazole, fenbendazole, oxfendazole, albendazole, cyclobendazole, febantel, thiophanate and the like. Additional anthelmintic agents include imidazothiazoles and

tetrahydropyrimidines such as tetramisole-levamisole, butamisole, pyrantel, pamoate, aoxantel or morantel.

Compounds of this invention may be co-administered with fipronil.

Compounds of this invention may be co-administered with an insect growth regulator with molt inhibiting activity such as lufenuron and the like.

Compounds of this invention may be co-administered with ecdysone agonist such as tebufenozide and the like, which induces premature molt and causes feeding to cease.

The co-administered compounds are given via routes, and in doses, that are customarily used for those compounds.

Also included in the present invention are pharmaceutical compositions containing a compound of the present invention in combination with an anthelmintic agent, fipronil, an insect growth regulator, or a ecdysone agonist.

The following examples are provided to more fully illustrate the present invention, and shall not be construed as limiting the scope in any manner.

EXAMPLE 39

N-(2-Hydroxyethyl)-31-hydroxy-20,30-oxa-29,30,31,32-tetrahydro-nodulisporamide

To 1 mg Compound C in 1 mL methylene chloride at room temperature was added 1 drop diisopropylethylamine, 1 drop $HOCH_2CH_2NH_2$, 3 mg N-hydroxybenzotriazole and 3 mg PyBOP. After 15 minutes, the reaction was quenched with 2 mL saturated $NaHCO_3$, extracted with ethyl acetate, dried with Na_2SO_4, filtered and concentrated in vacuo. The crude was purified by reversed-phase HPLC using first 20:80 water/methanol as eluant and the purified product was characterized by ^1H NMR.

Example 40

N-tert-Butyl Nodulisporamide

To a solution of 30 mg of nodulisporic acid in 3 mL methylene chloride at 0 °C was added 0.03 mL triethylamine and 12 mg N-hydroxybenzotriazole followed by 28 mg BOP reagent. The solution was stirred for 10 minutes and then 0.05 mL tert-butylamine was added. The solution was stirred overnight at 4 °C and then poured into 1/1 saturated sodium bicarbonate/brine, extracted with methylene chloride and the combined organic layers dried over sodium sulfate. The solids were removed by filtration and the solution concentrated to dryness under reduced pressure. The residue was partially purified by preparative TLC

on silica gel (one 1000 micron plate) using 1/2 acetone/hexanes as eluant. Additional purification using HPLC (6/4 acetonitrile/water for 15 minutes, then a 45 minute linear gradient to 7/3 acetontrile/water) yielded pure product (17 mg). The purified product was characterized by proton NMR and MS (m/z: 735.7 (M+1)).

The general procedure of Example 40 was repeated using the appropriate amines listed in Table 3 below to provide the corresponding monosubstituted nodulisporamide compounds. These compounds were characterized by proton NMR and/or mass spectrometry (unless otherwise specified, m/z is for M+1).

General Procedure for the Preparation of Additional Amide Derivatives of Nodulisporic Acid

To a solution of 30 mg of nodulisporic acid in 3 mL methylene chloride at 0 °C add 0.03 mL triethylamine and 12 mg N-hydroxybenzotriazole followed by 28 mg BOP reagent. Stir the solution for 10 minutes and then add 50 mg of amine selected from Table 5. Stir the solution overnight at 4 °C and then pour into 1/1 saturated sodium bicarbonate/brine, extract with methylene chloride and dry the combined organic layers over sodium sulfate. Remove the solids by filtration and concentrate the solution to dryness under reduced pressure. Pure product may be obtained by flash chromatography or preparative TLC on silica gel or reversed-phase liquid chromatography. The purified product may be characterized by proton NMR and mass spectrometry.

EXAMPLE 308

General Procedure for the Preparation of 29,30,31,32-Tetrahydro-nodulisporic Acid Derivatives

Place 50 mg of a nodulisporamide or nodulisporate analog prepared from the amines listed in Table 6 or the alcohols listed in Table 2 in 4 mL methanol at room temperature. Hydrogenation may be accomplished using 10% Pd on carbon under 1 atmosphere of hydrogen from 15 minutes to 24 hours. The catalyst may be removed by filtration through a pad of Celite using methanol as eluant. Concentration of the solution under reduced pressure followed by purification on silica gel by either flash chromatography, preparative TLC or by reversed-phase liquid chromatography will yield the desired corresponding 29,30,31,32-tetrahydro derivative.

Alternatively, place 50 mg nodulisporic acid in 4 mL methanol at room temperature. Add 1 to 50 mg 10% Pd on carbon and establish an atmosphere of hydrogen using a balloon for 15 minutes to 24 hours. The catalyst may be subsequently removed by filtration through a pad of Celite using methanol as eluant. Concentration of the solution under reduced pressure followed by purification on silica gel by either flash chromatography, preparative TLC or by reversed-phase liquid chromatography will yield the desired corresponding 29,30,31,32-tetrahydro-nodulisporic acid. The 29,30,31,32-tetrahydro-nodulisporic acid thus obtained may be coupled to the amines in Table 6 or the alcohols listed in Table 2 to form the desired 29,30,31,32-tetrahydro-amide and ester derivatives.

EXAMPLE 309
29,30-Dihydro-nodulisporic acid

To 1 mg of nodulisporic acid in 1 mL of dichloromethane was added 1.6 mg of Wilkinson's catalyst. The mixture was stirred under a balloon atmosphere of hydrogen overnight (18 h). HPLC separation was obtained with a Magnum 9-ODS reverse phase column and 85:15 methanol:water to 100% methanol gradient. The purified product was isolated upon evaporation of the solvent and characterized by its ^1H NMR.

EXAMPLE 311
General Procedure for the Preparation of 29,30-Dihydro-Nodulisporic Acid Derivatives

To a solution of 30 mg of 29,30-dihydro-nodulisporic acid in 3 mL methylene chloride at 0 °C add 0.03 mL triethylamine and 12 mg N-hydroxybenzotriazole followed by 28 mg BOP reagent. Stir the solution for 10 minutes and then add 50 mg of an amine or an alcohol selected from Table 6. Stir overnight at 4 °C and then at room temperature for 2 hours. Pour the solution into 1/1 saturated sodium bicarbonate/brine. Extract the solution with methylene chloride and dry the combined organic layers over sodium sulfate. Remove the solids by filtration and concentrate the solution under reduced pressure. Pure product may be obtained following purification by flash chromatography, preparative TLC or reversed-phase liquid chromatography. Products may be characterized by proton NMR and or mass spectrometry.

EXAMPLE 312
General Procedure for the Preparation of 31,32-Dihydro-Compound B Derivatives

Place 50 mg of a ester or amide analog prepared from compound B and the amines listed in Table 6 or alcohols listed in Table 2 in 4 mL methanol at room temperature. Hydrogenation of the 31,32-double bond may be accomplished using 10% Pd on carbon under 1 atmosphere of hydrogen from 15 minutes to 24 hours. The catalyst may be removed by filtration through a pad of Celite using methanol as eluant. Concentration of the solution under reduced pressure followed by purification on silica gel by either flash chromatography, preparative TLC or by reversed-phase liquid chromatography will yield the desired 31,32-dihydro-Compound B derivative.

Alternatively, place 50 mg compound B in 4 mL methanol at room temperature. Add 1 to 50 mg 10% Pd on carbon and establish an atmosphere of hydrogen using a balloon for 15 minutes to 24 hours. The catalyst may be subsequently removed by filtration through a pad of Celite using methanol as eluant. Concentration of the solution under reduced pressure followed by purification on silica gel by either flash chromatography, preparative TLC or by reversed-phase liquid chromatography will yield the desired corresponding 31,32-dihydro-compound B. The 31,32-dihydro-compound B thus formed may be coupled to the amines listed in Table 6 and the alcohols listed in Table 2 to form the desired 31,32-dihydro-compound B amides and esters.
